### **Abstract**

The present study aims to investigation for Newcastle disease (ND) in wild pigeons was carried out in 100 serum sample were examined for evaluating of Antibody titers. Haemagglutination-inhibition (HI) was used for detection and quantification of antibodies against Newcastle Disease (ND) virus .The results showed that (NDV) were detected in 17% (n = 100) of serum samples collected from pigeons, while 83% non-detectable of (NDV) antibodies. Studies have shown that pigeons are susceptible to NDV. The risk of the transmission of NDV pigeons to poultry. Therefore there is a need to conduct regular and strategic vaccination programs against ND for poultry.

**Key words:** Newcastle Disease Virus, Wild Pigeon, Antibody, HA,HI test.

### **Introduction**

Newcastle disease (ND) is a highly contagious viral disease of Poultry , wild and captive birds with high morbidity and mortality caused by the serotype avian paramyxovirus type I (APMV-I), member of the genus Avulavirus in the family Paramyxoviridae (Beard *et al.*,1984, Mayo,2002).In Iraq, (Al-Jumaily *et al.*, 1989) presented evidence that the population of the rock pigeon carry such dangerous disease agents as the bacterium *Salmonella typhimurium* and Newcastle virus. However (Alexander *et al.*, 1984) reported that the spread of ND virus to chickens has occurred in several countries as a result of feed contaminated by the feces of ND infected pigeons as well as (Dilaveris *et al.*,2007) reported that unvaccinated birds can become infected by NDV of pigeon origin, as exemplified by the 2006 case of ND in Scotland. Over 200 species of birds have been reported to be susceptible to natural

and/or experimental infection with ND virus and it seems probable that more are fully susceptible (Alexander, 1999). Although many species of bird are susceptible to ND it occurs mainly in galliformes such as pheasants, partridges and quails and also in birds of prey, including owls, pigeons and psittaciformes. In most species of bird the young are more susceptible than the adult (Arnall and Keymer, 1975). It is characterized by nasal and ocular discharge, yellowish to greenish diarrhea, sneezing, coughing, drooping of wings, twisting of head, drop in egg production and thin shelled eggs, complete paralysis, weakness and sudden death (Chansiripomchai and Sasipreyayan,

2006; Roy and Chamham, 2007). Pigeons are amongst the most prevalent and readily observable birds in all provinces of Iraq. Besides constituting small part of human food, they are used for ornamental or appearance purposes (fancy pigeons) as well as pets, human sport (racers and performers), for biological and medical experimentations, and for teaching the art of taxidermy. Pigeons in this part of the world also have a rich historical and anecdotal background, More importantly, pigeons pose a serious health threat to millions of people and some of their economic animals. However the study aimed to investigate of NDV in wild pigeons.

## **Materials and Methods**

**Study area:** The wild pigeons included in this study were survived on the building of two faculties (Agriculture and Veterinary Medicine) at University of Duhok which located in Sumel district, west of Duhok City, Kurdistan region, Iraq. A total of 100 Adults different aged pigeons were captured with a fine mesh net at different times between March and August 2012. Thereafter, the pigeons were caged and taken to the Animal house at faculty of Veterinary Medicine.

**Serum collection:** 100 blood samples were aseptically collected from brachial vein (wing vein) of pigeons, 2 ml of fresh blood put in a test tube without anticoagulant from each bird then centrifuged at 1500 r.p.m, then the serum was separated and stored at freezing (- 20 °C) till time of tests.

## **Serological Procedure:**

**Preparation of washed red blood cells :** 3 ml of blood was collected from chicken (free from pathogens), put in test tube contains 1 ml of sodium citrate (4% solution) as an anticoagulant , then Centrifuge the whole blood at 3000 rpm for 5 minutes Remove plasma and buffy coat layer. 5ml of normal saline (1% NaCl) with was added to volume of the red cells, and invert the tube to mix. Centrifuge for 5 minutes at 2000 rpm and discard the supernatant. Then repeat adding of normal saline for 3 washes or until the supernatant is clear Completely remove the supernatant and freeze the red cells at -20°C, (Allan and Gough, 1974)

**Haemagglutination test (HA):** The HA titres of the ND antigen were determined and diluted to contain 4-HA units. This concentration was used for the HI test as described by (Allan and Gough, 1974), and (Allan *et al.*,1978), In this test ( LaSota strain) of NDV was used as the source of antigen for the HI test using 4 haemagglutinating(HA) units through using microtiter plate consist of 96 wells V shaped -bottom microtiter plate.

1-0.025 ml of isotonic solution (normal saline) were added to all wells (96) equally via using multiple channel micropipete.

2-0.025 ml of lasota strain (Antigen) was added to the first well of each row of column 1 then making several dilution applied until reaching the last well.

3-0.025 ml of washed RBCs(1%) were added to all wells ,then shaking the plat in all direction via using shaker instrument after that the plat put in incubator 37C° for 15 mints then the result was recorded. Furthermore the last column of each microtiter plate used for control positive and negative in case positive control 3 wells Contains normal saline ,Ag and WRBCs) which represented as a hazy film of red blood cells, no button or a very a small button of red blood cells at the bottom of the V-bottom wells. another 3 wells negative control Contains( Normal saline and WRBCs) .which showing that A sharp button of red blood cells at the bottom of the V-bottom wells.

**Haemagglutination Inhibition test (HI):**, The HI tests were done by the beta-procedure in V-bottom microtiter plate as described(Stephan and Beard 1998).thawing of serum samples at 56 C° ,the titer of Abs in serum sample were evaluated against (NDV) as follow.

1-0.025 ml of isotonic solution (normal saline ) were added to all wells (96) equally via using multichannel micropipete .

2-0.025 ml of serum sample for (case 1) was added to the first well of each row of column 1 then making several dilution for serum across the microtiter plate until reaching the last well.

3-0.025 ml of 4HAU of virus/antigen volume were added to all wells and mix gently then put it in side incubator for 15 minutes at 37C° or leave it in minimum of 30 minutes at room temperature or 60 minutes at 4° C.

4-0.025 ml of washed RBCs (1%) were added to all wells via using multichannel microtiters ,then shaking the plat in all direction via using shaker instrument after that the plat put in incubator 37C° for 30 mints then the titers was recorded. Further more the last column of each microtiter plate used for control positive and negative in case positive control 3 wells Contains (normal saline, Ag,Ab and WRBCs) which showing that A sharp button of red blood cells at the bottom of the V-bottom wells. another 3 wells negative control Contains( Normal saline ,Ag and WRBCs). which represented as a hazy film of red blood cells, no button or a very a small button of red blood cells at the bottom of the V-bottom wells. The HI titre for each bird was determined and expressed in log<sub>2</sub>, and the geometric mean for each species was calculated. An HI titre  $\geq 2 \log_2$  was considered positive.

## **Results**

- 1- Clinical symptoms: during the process of inspection and examination of pigeons several abnormal clinical signs were seen like emaciation ,weakness ,turtle of neck, inappetance ,lameness ,ruffled feathers ,diarrhea ,depression, nasal discharge, ataxia and reluctant to move.
- 2- The result of HI test on the sera is showed that out of the 100 sera samples screened for NDV in wild pigeons, 17 (17 %) sera samples representing were positive for NDV-HI antibodies while 83 (83%) sera samples were negative.

## **Discussion**

There was serological evidence of NDV antibodies in pigeons in presented study. This might be due to occasional visits of these birds to the poultry premises where they could have contracted the virus from materials from poultry houses Research farm and mixing of wild pigeon with domesticated birds of nearing village (were the infection of ND is endemic). Pigeons and doves are among a group of domesticated birds that were primarily affected by the third panzootic of ND which apparently arose in the Middle East in the late 1970s (Kaleta *et al.*,1985). The disease spread to all parts of the world, largely as a result of contact between birds atraces and shows and the large international trade in such birds (Biancifiori and Fioroni, 1983).In Iraq (Anton AL-Bana *et al.*, 2007) showed that in a study about isolation and identification of Newcastle disease virus from wild pigeons there is no detectable of Ab titers by using (HI) test directly, with finding of clinical signs of disease this may be due to acute infection. On the basis of ND virulence, Newcastle disease virus (NDV) has been classified into three strains viz. velogenic, mesogenic and lentogenic. These strains produce highly acute, moderate and mild type of infection in poultry, respectively (Saif, 2003),as well as present study detectable of Ab titers , another study (kamas,1981) reported that pigeons infected experimentally with NDV which mean the infection could be transmitted from pigeons to poultry. While a study in Tanzania Phlemon (2010) results showed that 10% of serum sample were positive of NDV in domesticated pigeons due to mixing with poultry. In Nigeria (Fagbohun *et al*(2000) represented that there was no serological evidence of ND in pigeons his work, this may be due dealing with small number of pigeons.

## **Conclusion**

Wild pigeons can tolerate certain disease agents as well as reservoir for spreading many parasitic and microbial species to other types of birds especially (Poultry), without displaying gross pathological changes and clinical signs of sickness. Therefore, eradication of pigeons from around the poultry breeding and layer farms as well as from food and water handling facilities is an essential factor for counteracting disease dissemination.

#### الخلاصة

هذه الدراسة تهدف لغرض الكشف عن المرض نيوكاسل (الفايروسية) في الحمامات البرية. اخذت 100 عينة من السائل المصلي الدموي بعد ذلك تم اجراء الفحص المختبري لتقييم معيار للاجسام المضاده عن طريق استخدام اختبار المصلي (اج-ائ) حيث استخدم هذا الاختبار لقياس نوعيه وكميه الاجسام المضاده. وكانت النتيجة وجود معايير للاجسام المضاده ضد هذا المرض في 17 (17%) عينة الماخوذه من مجموع الحمام البري. بينما 83 (83%) عينة عدم وجود الاجسام المناعيه فيها. مع وجود حدوث للنقل هذا المرض الى الطيور الداجنه لذلك الحاجه الماسه لغرض تطبيق برنامج للتلقيح ضد مرض نيوكاسل في الدواجن.
